MACHINE LEARNING

ERNEST YEUNG ERNESTYALUMNI@GMAIL.COM

From the beginning of 2016, I decided to cease all explicit crowdfunding for any of my materials on physics, math. I failed to raise *any* funds from previous crowdfunding efforts. I decided that if I was going to live in *abundance*, I must lose a scarcity attitude. I am committed to keeping all of my material **open-sourced**. I give all my stuff *for free*.

In the beginning of 2017, I received a very generous donation from a reader from Norway who found these notes useful, through *PayPal*. If you find these notes useful, feel free to donate directly and easily through PayPal, which won't go through a 3rd. party such as indiegogo, kickstarter, patreon. Otherwise, under the *open-source MIT license*, feel free to copy, edit, paste, make your own versions, share, use as you wish.

Date: 24 avril 2016.
Key words and phrases. Machine Learning, statistical inference, statistical inference learning.

Abstract. Everything about Machine Learning.

Part 1. Data; Data Wrangling, Data cleaning, Web crawling, Data input

1. Sample, example data; input data

1.1. **sklearn, from sci-kit learn, sample data, datasets.** cf. `sampleinputdataX_sklearn.ipynb`
For $j = 0, 1, \dots d-1$, $d =$ number of "features",

$$x_i^{(j)} \in (\mathbb{R}^N)^d = \underbrace{\mathbb{R}^N \times \mathbb{R}^N \times \cdots \times \mathbb{R}^N}_{d}$$

e.g. $N = 442$ (number of given observations/data)
$y_i \in \mathbb{R}^N$ (represents target or result)
Given data $(x_i^{(j)}, y_i) \in (\mathbb{R}^N)^d \times \mathbb{R}^N$,
we can restrict data $(x_i^{(j)}, y_i)$ to subsets to train and test, for training and testing.
So let $I_{\text{train}}, I_{\text{test}} \subset \{0, 1, \dots N-1\}$ s.t. $I_{\text{train}} \cap I_{\text{test}} = \emptyset$.
Want:

$$(x_i^{(j)}, y_i)_{i \in I_{\text{train}}} \mapsto \theta_\alpha$$
$$(\mathbb{R}^{|I_{\text{train}}|})^d \times \mathbb{R}^{|I_{\text{train}}|} \to \mathbb{R}^{|d|}$$

and so further, I think the idea is

$$(x_i^{(j)}, y_i)_{i \in I_{\text{test}}} \xrightarrow{L_{\theta_\alpha}} L_{\theta_\alpha}(\theta_\alpha(x_i^{(j)}, y_i))$$
$$(\mathbb{R}^{|I_{\text{test}}|})^d \times \mathbb{R}^{|I_{\text{test}}|} \to \mathbb{R}$$

Part 2. Introduction

1.1.1. *Terminology.*
inputs ≡ independent variables ≡ predictors (cf. statistics) ≡ features (cf. pattern recognition)
outputs ≡ dependent variables ≡ responses
cf. Chapter 2 Overview of Supervised Learning, Section 2.1 Introduction of Hastie, Tibshirani, and Friedman (2009) [1]
cf. Chapter 2 Overview of Supervised Learning, Section 2.2 Variable Types and Terminology of Hastie, Tibshirani, and Friedman (2009) [1]

1.1.2. *FinSet.*
The category FinSet ∈ Cat is the category of all finite sets (i.e. Obj(FinSet) ≡ all finite sets) and all functions in between them; note that FinSet ⊂ Set [1]
Recall that the FinSet *skeletal* is

1.2. **Supervised Learning.** cf. http://cs229.stanford.edu/notes/cs229-notes1.pdf
Consider data to belong to the category of all possible data:

$$\text{Data} \equiv \text{Dat} = (\text{Obj}(\text{Dat}), \text{MorDat}, 1, \circ), \qquad \text{Dat} \in \text{Cat}$$

Consider the **training set**:

$$\text{training set} := \{(x^{(i)}, y^{(i)}) | i = 1 \dots m, x^{(i)} \in \mathcal{X}, y^{(i)} \in \mathcal{Y}\}$$

where $\mathcal{X}$ is a manifold (it can be topological or smooth, EY:20160502 I don't know exactly because I need to check the topological and/or differential structure); $\mathcal{Y} \in \text{Obj}(\text{FinSet})$, or ($\mathcal{Y} \in \text{Obj}(\text{Top})$(or $\mathcal{Y} \in \text{Obj}(\text{Man})$)).
So training set $\subset \mathcal{X} \times \mathcal{Y} \in \text{Obj}(\text{Dat})$.
I propose that there should be a functor H that represents the "learning algorithm":

$$\text{Dat} \xrightarrow{H} \text{ML}$$

s.t.

$$H : \mathcal{X} \times \mathcal{Y} \to \text{Hom}(\mathcal{X}, \mathcal{Y})$$
$$H(\text{training set}) = H(\{(x^{(i)}, y^{(i)}) | i = 1 \dots m\}) = h$$

When $\mathcal{Y} \in \text{Obj}(\text{FinSet})$, *classification.*
When $\mathcal{Y} \in \text{Obj}(\text{Top})$ (or Obj(Man), *regression.*

1.2.1. *Linear Regression.* Keeping in mind

$$\text{Dat} \xrightarrow{H} \text{ML}$$

Consider

$$h : \mathbb{R}^p \to \text{Hom}(\mathcal{X}, \mathcal{Y})$$
$$h : \theta \mapsto h_\theta$$

s.t.

$$h_\theta : \mathcal{X} \to \mathcal{Y}$$

so (possibly) $h \in \text{Obj}ML$ (or is h part of the functor H?)
Consider the cost function J

$$J : \mathbb{R}^p \to \text{Hom}(\mathfrak{X} \times \mathfrak{Y}, \mathbb{R}) = C^\infty(\mathcal{X} \times \mathcal{Y})$$
$$J(\theta) = \frac{1}{2} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)})^2$$

1.2.2. *LMS algorithm (least mean square (or Widrow-Hoff learning rule)).* Define **gradient descent** algorithm:

$$\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta)$$

with := being assignment (I'll use := for "define", in mathematical terms, use context to distinguish the 2), where α is the *learning rate.*
Rewriting the above,

$$\theta := \theta - \alpha \text{grad} J(\theta)$$

where $\text{grad} : C^\infty(M) \to \mathfrak{X}(M)$, with M being a smooth manifold.
This is *batch gradient descent*:

$$\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta) = \theta_j - \alpha \frac{\partial}{\partial \theta_j} \frac{1}{2} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)})^2 = \theta_j - \alpha \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)}) \left(\frac{\partial h_\theta(x^{(i)})}{\partial \theta} \right)$$

Simply notice how the entire training set of m rows is used.

[1] nlab FinSet https://ncatlab.org/nlab/show/FinSet

I will expound on the so-called distinguished object $1 \xrightarrow{P} X$ on pp. 8, in Section 2 The Category of Conditional Probabilities of Culbertson and Sturtz (2013) [2] because it wasn't clear to me in the first place (the fault is mine; the authors wrote a very lucid and very fathomable, pedagogically-friendly exposition).

$\forall Y$ with indiscrete σ-algebra $\Sigma_Y = \{Y, \emptyset\}$
(remember, $((Y, \Sigma_Y), \mu_Y)$, $\mu_Y(\phi) = 0$, $\mu_Y(Y) = 1$),

$\exists!$ unique morphism in Mor$\mathcal{P}$, $X \to Y$, since
$\forall\, P : X \to Y$, $P \in \text{Mor}\mathcal{P}$, P_x must be a probability measure on Y, because

$$(X, \Sigma_X) \xrightarrow{P} (Y, \Sigma_Y)$$
$$P : \Sigma_Y \times X \to [0,1]$$
$$P(\cdot|x) : \Sigma_Y \to [0,1] \equiv \begin{array}{l} P_x : \Sigma_Y \to [0,1] \text{ s.t.} \\ P_x(\emptyset) = 0,\ P_x(Y) = 1 \end{array}$$

i.e. EY: 20160503, Given $x \in X$ occurs, Y must occur.

By def. of terminal object $(\forall\, (X, \Sigma_X) \in \text{Obj}\mathcal{P}$, $\exists!$ morphism P s.t. $(X, \Sigma_X) \xrightarrow{P} (Y, \Sigma_Y)$,
Y *terminal* object, and denote unique morphism $!_X : X \to Y$, $!_X \in \text{Mor}\mathcal{P}$.

Up to isomorphism, canonical terminal object is 1-element set denoted by $1 = \{*\}$, with the only possible σ-algebra $(\mu(*) = 1,\ \mu(\emptyset) = 0)$,

$$\forall\, P : 1 \to X,\ P \in \text{Mor}\mathcal{P},\ P \in \text{Hom}_{\mathcal{P}}(1, X),\ \forall\, X \in \text{Mor}\mathcal{P}$$

P is an "absolute" probability measure on X because "there's no variability (conditioning) possible within singleton set $1 = \{*\}$." [2]

Now

$$P : \Sigma_X \times 1 \to [0,1]$$
$$P(\cdot|*) : \Sigma_X \to [0,1]$$

where $P(\cdot|*) : \Sigma_X \to [0,1]$ perfect probability measure on X, $P(\cdot|*) : \Sigma_X \to [0,1] \equiv P_*$, i.e. $P(\cdot|*) = p(\cdot)$ (usual probability on X).

$\forall\, A \in \Sigma_X$, $P(A|\cdot) : 1 \to [0,1]$, but $P(A|*) = P(A)$, $P(A|\emptyset) = 0$.

Refer to

$$1 \xrightarrow{P} X$$

morphism $P : 1 \to X \in \text{Mor}\mathcal{P}$ as probability measure or distribution on X.

2. Deep Learning

Deep Learning Tutorial [6]

3. Parallel Computing

3.1. **Udacity Intro to Parallel Programming : Lesson 1 - The GPU Programming Model.** Owens and Luebki pound fists at the end of this video. =)))) Intro to the class.

3.1.1. *Running CUDA locally.* Also, Intro to the class, in Lesson 1 - The GPU Programming Model, has links to documentation for running CUDA locally; in particular, for Linux: `http://docs.nvidia.com/cuda/cuda-getting-started-guide-for-linux/index.html`. That guide told me to go download the NVIDIA CUDA Toolkit, which is the https://developer.nvidia.com/cuda-downloads.

For *Fedora*, I chose Installer Type `runfile (local)`.

Afterwards, installation of CUDA on Fedora 23 workstation had been nontrivial. Go see either my github repository ML-grabbag (which will be updated) or my wordpress blog (which may not be upgraded frequently).

$P = VI = I^2R$ heating.

3.1.2. *Definitions of Latency and throughput (or bandwidth).* cf. Building a Power Efficient Processor
Latency vs Bandwidth

latency [sec]. From the title "Latency vs. bandwidth", I'm thinking that throughput = bandwidth (???). throughput = job/time (of job).

Given total task, velocity v,
total task $/v$ = latency. throughput = latency/(jobs per total task).

Also, in Building a Power Efficient Processor. Owens recommends the article David Patterson, "Latency..."

cf. GPU from the Point of View of the Developer

$n_{\text{core}} \equiv$ number of cores
$n_{\text{vecop}} \equiv (n_{\text{vecop}}-$wide axial vector operations$/$*core* core)
$n_{\text{thread}} \equiv$ threads/core (hyperthreading)

$$n_{\text{core}} \cdot n_{\text{vecop}} \cdot n_{\text{thread}} \text{ parallelism}$$

There were various websites that I looked up to try to find out the capabilities of my video card, but so far, I've only found these commands (and I'll print out the resulting output):

```
$ lspci -vnn | grep VGA -A 12

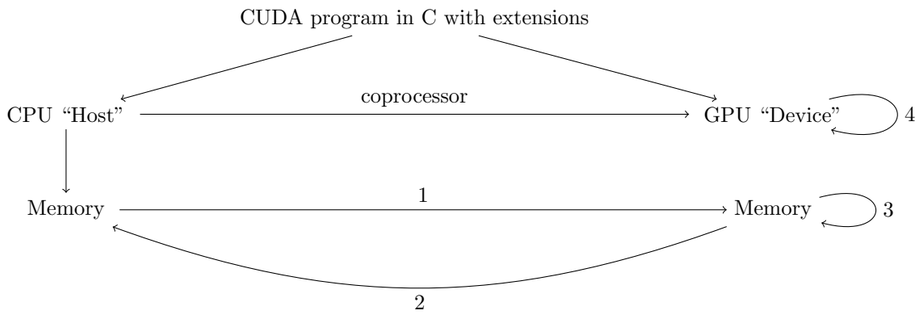
CUDA Program Diagram



CPU "host" is the boss (and issues commands) -Owen.
Coprocessor : CPU "host" $\to$ GPU "device"
Coprocessor : CPU process $\mapsto$ (co)-process out to GPU

With

1 data cpu $\to$ gpu
2 data gpu $\to$ cpu (initiated by cpu host)

1., 2., uses `cudaMemcpy`
3 allocate GPU memory: `cudaMalloc`
4 launch kernel on GPU

Remember that for 4., this launching of the kernel, while it's acting on GPU "device" onto itself, it's initiated by the boss, the CPU "host".

Hence, cf. Quiz: What Can GPU Do in CUDA, GPUs can respond to CPU request to receive and send Data CPU $\to$ GPU and Data GPU $\to$ CPU, respectively (1,2, respectively), and compute a kernel launched by the CPU (3).

A CUDA Program A typical GPU program

- `cudaMalloc` - CPU allocates storage on GPU
- `cudaMemcpy` - CPU copies input data from CPU $\to$ GPU
- *kernel launch* - CPU launches kernel(s) on GPU to process the data
- `cudaMemcpy` - CPU copies results back to CPU from GPU

Owens advises minimizing "communication" as much as possible (e.g. the `cudaMemcpy` between CPU and GPU), and do a lot of computation in the CPU and GPU, each separately.

Defining the GPU Computation

Owens circled this

BIG IDEA | This is Important

Kernels look like serial programs

Write your program as if it will run on **one** thread

The GPU will run that program on **many** threads

Squaring A Number on the CPU

Note

(1) Only 1 thread of execution: ("thread" := one independent path of execution through the code) e.g. the `for` loop
(2) no explicit parallelism; it's serial code e.g. the `for` loop through 64 elements in an array

GPU Code A High Level View

CPU:

- Allocate Memory
- Copy Data to/from GPU
- Launch Kernel - species degree of parallelism

GPU:

- Express Out = In $\cdot$ In - says *nothing* about the degree of parallelism

Owens reiterates that in the GPU, everything looks serial, but it's only in the CPU that anything parallel is specified.
pseudocode: CPU code: square kernel <<< 64 >>> (outArray,inArray)

Squaring Numbers Using CUDA Part 3

From the example

```
// launch the kernel
square<<<1, ARRAY_SIZE>>>(d_out , d_in)
```

we're introduced to the "CUDA launch operator", initiating a kernel of 1 block of 64 elements (`ARRAY_SIZE` is 64) on the GPU. Remember that `d_` prefix (this is naming comvention) tells us it's on the device, the GPU, solely.

With CUDA launch operator $\equiv$<<<>>>, then also looking at this explanation on `stackexchange` (so surely others are confused as well, of those who are learning this (cf. CUDA kernel launch parameters explained right?). From Eric's answer,

threads are grouped into blocks. all the threads will execute the invoked kernel function.
Certainly,

$$<<<>>>: (n_{\text{block}}, n_{\text{threads}}) \times \text{kernelfunctions} \mapsto \text{kernelfunction} <<< n_{\text{block}}, n_{\text{threads}} >>> \in \text{End} : \text{Dat}_{\text{GPU}}$$

$$<<<>>>: \mathbb{N}^+ \times \mathbb{N}^+ \times \text{Mor}_{\text{GPU}} \to \text{EndDat}_{\text{GPU}}$$

where I propose that GPU can be modeled as a category containing objects Dat_{GPU}, the collection of all possible data inputs and outputs into the GPU, and Mor_{GPU}, the collection of all kernel functions that run (exclusively, and this *must* be the class, as reiterated by Prof. Owen) on the GPU.

Next,

$$\text{kernelfunction} <<< n_{\text{block}}, n_{\text{threads}} >>>: \text{din} \mapsto \text{dout} \qquad \text{(as given in the "square" example, and so I propose)}$$

$$\text{kernelfunction} <<< n_{\text{block}}, n_{\text{threads}} >>>: (\mathbb{N}^+)^{n_{\text{threads}}} \to (\mathbb{N}^+)^{n_{\text{threads}}}$$

But keep in mind that dout, din are pointers in the C program, pointers to the place in the memory.

`cudaMemcopy` is a functor category, s.t. e.g. $\text{Obj}_{\text{CudaMemcopy}} \ni \text{cudaMemcpyDevicetoHost}$ where

$$\text{cudaMemcopy}(-, -, n_{\text{thread}}, \text{cudaMemcpyDeviceToHost}) : \text{Memory}_{\text{GPU}} \to \text{Memory}_{\text{CPU}} \in \text{Hom}(\text{Memory}_{\text{GPU}}, \text{Memory}_{\text{CPU}})$$

Squaring Numbers Using CUDA 4

Note the C language construct *declaration specifier* - denotes that this is a kernel (for the GPU) and not CPU code. Pointers need to be allocated on the GPU (otherwise your program will crash spectacularly -Prof. Owen).

3.1.3. *What are C pointers?* Is $\langle$ type $\rangle *$, a pointer, then a mapping from the category, namely the objects of types, to a mapping from the specified value type to a memory address?

e.g.

$$\langle\rangle * : \text{float} \mapsto \text{float} *$$

$$\text{float} * : \text{din} \mapsto \text{ some memory address}$$

and then we pass in mappings, not values, and so we're actually declaring a square *functor*.

What is `threadIdx`? What is it mathematically? Consider that $\exists$ 3 "modules":

$$\text{threadIdx}.x$$
$$\text{threadIdx}.y$$
$$\text{threadIdx}.z$$

And then the line

```
int idx = threadIdx.x;
```

says that idx is an integer, "declares" it to be so, and then assigns idx to threadIdx.x which surely has to also have the same type, integer. So (perhaps)

$$idx \equiv \text{threadIdx}.x \in \mathbb{Z}$$

is the same thing.

Then suppose threadIdx $\subset$ FinSet, a subcategory of the category of all (possible) finite sets, s.t. threadIdx has 3 particular morphisms, $x, y, z \in \text{Mor}\mathit{threadIdx}$,

$$x : \text{threadIdx} \mapsto \text{threadIdx}.x \in \text{Obj}_{\text{FinSet}}$$
$$y : \text{threadIdx} \mapsto \text{threadIdx}.x \in \text{Obj}_{\text{FinSet}}$$
$$z : \text{threadIdx} \mapsto \text{threadIdx}.x \in \text{Obj}_{\text{FinSet}}$$

Configuring the Kernel Launch Parameters Part 1

n_{blocks}, n_{threads} with $n_{\text{threads}} \geq 1024$ (this maximum constant is GPU dependent). You should pick the $(n_{\text{blocks}}, n_{\text{threads}})$ that makes sense for your problem, says Prof. Owen.

3.1.4. *Memory layout of blocks and threads.* $\forall\, (n_{\text{blocks}}, n_{\text{threads}}) \in \mathbb{Z} \times \{1 \dots 1024\}$, $\{1 \dots n_{\text{block}} \times \{1 \dots n_{\text{threads}}\}$ is now an ordered index (with lexicographical ordering). This is just 1-dimensional (so possibly there's a 1-to-1 mapping to a finite subset of $\mathbb{Z}$).

I propose that "adding another dimension" or the 2-dimension, that Prof. Owen mentions is being able to do the Cartesian product, up to 3 Cartesian products, of the block-thread index.

Quiz: Configuring the Kernel Launch Parameters 2

Most general syntax:

Configuring the kernel launch

```
kernel<<<grid of blocks, block of threads >>>(...)

// for example

square<<<dim3(bx,by,bz), dim3(tx,ty,tz), shmem>>>(...)
```

where `dim3(tx,ty,tz)` is the grid of blocks $bx \cdot by \cdot bz$
`{dim3}(tx,ty,tz)` is the block of threads $tx \cdot ty \cdot tz$
`shmem` is the shared memory per block in bytes

Problem Set 1 "Also, the image is represented as an 1D array in the kernel, not a 2D array like I mentioned in the video."

Here's part of that code for squaring numbers:

```
__global__ void square(float *d_out, float *d_in) {
  int idx = threadIdx.x;
  float f = d_in[idx];
  d_out[idx] = f*f;
  }
```

3.1.5. *Grid of blocks, block of threads, thread that's indexed; (mathematical) structure of it all.* Let

$$\text{grid} = \prod_{I=1}^{N} (\text{block})^{n_I^{\text{block}}}$$

where $N = 1, 2, 3$ (for CUDA) and by naming convention $\begin{matrix} I = 1 \equiv x \\ I = 2 \equiv y \\ I = 3 \equiv z \end{matrix}$

Let's try to make it explicity (as others had difficulty understanding the grid, block, thread model, cf. colored image to greyscale image using CUDA parallel processing, Cuda gridDim and blockDim) through commutative diagrams and categories (from math):

$$\begin{array}{ccc} \prod_{I=1}^{N} \mathbb{Z}^+ & & \ni (N_x^{\text{blocks}}, N_y^{\text{blocks}}, N_z^{\text{blocks}}) \\ \text{gridDim} \circlearrowright \downarrow \text{dim3} & & \text{dim3} \downarrow \circlearrowright (\text{gridDim}.x,\ \text{gridDim}.y,\ \text{gridDim}.z) \\ \text{grid} & & \ni \text{gridSize}(N_x^{\text{blocks}}, N_y^{\text{blocks}}, N_z^{\text{blocks}}) \end{array}$$

$$\begin{array}{ccc} \text{grid} & & \ni \texttt{d\_rgbaImage} \\ \downarrow \text{blockIdx} & & \downarrow (\text{blockIdx}.x,\text{blockIdx}.y,\text{blockIdx}.z) \\ \prod_{I=1}^{N} \mathbb{Z} \supset \prod_{I=1}^{N} \{1 \dots N_I^{\text{blocks}}\} & & \ni (i^{\text{blocks}}, j^{\text{blocks}}, k^{\text{blocks}}) \end{array}$$

and then similar relations (i.e. arrows, i.e. relations) go for a block of threads:

$$\begin{array}{ccc} \prod_{I=1}^{N} \mathbb{Z}^+ & & \ni (N_x^{\text{threads}}, N_y^{\text{threads}}, N_z^{\text{threads}}) \\ \text{blockDim} \circlearrowright \downarrow \text{dim3} & & \text{dim3} \downarrow \circlearrowright (\text{blockDim}.x,\ \text{blockDim}.y,\ \text{blockDim}.z) \\ \text{block} & & \ni \text{blockSize}(N_x^{\text{threads}}, N_y^{\text{threads}}, N_z^{\text{threads}}) \end{array}$$

$$\begin{array}{ccc} \text{block} & & \ni \text{block} \\ \downarrow \text{threadIdx} & & \downarrow (\text{threadIdx}.x,\text{threadIdx}.y,\text{threadIdx}.z) \\ \prod_{I=1}^{N} \mathbb{Z} \supset \prod_{I=1}^{N} \{1 \dots N_I^{\text{threads}}\} & & \ni (i^{\text{threads}}, j^{\text{threads}}, k^{\text{threads}}) \end{array}$$

gridsize help assignment 1 Pp explains how threads per block is variable, and remember how Owens said Luebki says that a GPU doesn't get up for more than a 1000 threads per block.

3.1.6. *Generalizing the model of an image.* Consider vector space V, e.g. $\dim V = 4$, vector space V over field $\mathbb{K}$, so $V = \mathbb{K}^{\dim V}$.

Each pixel represented by $\forall\, v \in V$.

Consider an image, or space, M. $\dim M = 2$ (image), $\dim M = 3$. Consider a local chart (that happens to be global in our case):

$$\varphi : M \to \mathbb{Z}^{\dim M} \supset \{1 \dots N_1\} \times \{1 \dots N_2\} \times \cdots \times \{1 \dots N_{\dim M}\}$$
$$\varphi : x \mapsto (x^1(x), x^2(x), \dots, x^{\dim M}(x))$$

$$\begin{array}{ccc} E & \xrightarrow{\varphi} & M \times V \\ {\scriptstyle\pi}\downarrow & \swarrow & \\ M & & \end{array} \qquad \begin{array}{ccc} E & \xrightarrow{\varphi} & \text{grid} \times \text{ block of threads} \\ {\scriptstyle\pi}\downarrow & \swarrow & \\ \text{grid} & & \end{array}$$

Consider a "coarsing" of underlying M:

$$\begin{array}{ccc} M \times V & \xrightarrow{\text{proj}} & \text{proj}(M) \times \text{proj}(V) \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle\text{proj}(\pi)} \\ M = \{1 \dots N_1\} \times \{1 \dots N_2\} \times \cdots \times \{1 \dots N_{\dim M}\} & \xrightarrow{\text{proj}} & \text{proj}(M) = \{1 \dots \frac{N_1}{N_1^{\text{threads}}}\} \times \{1 \dots \frac{N_2}{N_2^{\text{threads}}}\} \times \cdots \times \{1 \dots \frac{N_{\dim M}}{N_{\dim M}^{\text{threads}}}\} \end{array}$$

e.g. $N_1^{\text{thread}} = 12$

$N_2^{\text{thread}} = 12$

Just note that in terms of syntax, you have the "block" model, in which you allocate blocks along each dimension. So in

$$const\ dim3\ blockSize(n_x^b, n_y^b, n_z^b)$$
$$const\ dim3\ gridSize(n_x^{\text{gr}}, n_y^{\text{gr}}, n_z^{\text{gr}})$$

Then the condition is $n_x^b/\dim V, n_y^b/\dim V, n_z^b/\dim V \in \mathbb{Z}$ (condition), $\qquad (n_x^{\text{gr}} - 1)/\dim V, n_y^{\text{gr}}/\dim V, n_z^{\text{gr}}/\dim V \in \mathbb{Z}$

Transpose Part 1

Now

$$\text{Mat}_{\mathbb{F}}(n,n) \xrightarrow{T} \text{Mat}_{\mathbb{F}}(n,n)$$
$$A \mapsto A^T \text{ s.t. } (A^T)_{ij} = A_{ji}$$
$$\text{Mat}_{\mathbb{F}} \xrightarrow{T} \mathbb{F}^{n^2}$$
$$A_{ij} \mapsto A_{ij} = A_{in+j}$$

$$\begin{array}{ccc} \text{Mat}_{\mathbb{F}}(n,n) & \longrightarrow & \mathbb{F}^{n^2} \\ {\scriptstyle T}\downarrow & & \downarrow{\scriptstyle T} \\ \text{Mat}_{\mathbb{F}}(n,n) & \longrightarrow & \mathbb{F}^{n^2} \end{array} \qquad \begin{array}{ccc} A_{ij} & \longmapsto & A_{in+j} \\ {\scriptstyle T}\downarrow & & \downarrow{\scriptstyle T} \\ (A^T)_{ij} = A_{ji} & \longmapsto & A_{jn+i} \end{array}$$

Transpose Part 2

Possibly, transpose is a functor.

Consider struct as a category. In this special case, Objstruct = {arrays} (a struct of arrays). Now this struct already has a hash table for indexing upon declaration (i.e. "creation"): so this category struct will need to be equipped with a "diagram" from the category of indices J to struct: $J \to$ struct.

So possibly

$$\begin{aligned} \text{struct} &\xrightarrow{T} && \text{array} \\ \text{ObjStruct} = \{ \text{ arrays } \} &\xrightarrow{T} && \text{Objarray} = \{ \text{ struct } \} \\ J \to \text{ struct} &\xrightarrow{T} && J \to \text{ array} \end{aligned}$$

Quiz: What Kind Of Communication Pattern This quiz made a few points that clarified the characteristics of these so-called communication patterns (amongst the memory?)

- map is bijective, and map : Idx → Idx
- gather - not necessarily surjective
- scatter - not necessarily surjective
- stencil - surjective
- transpose (see before)

Parallel Communication Patterns Recap

- map - bijective
- transpose - bijective
- gather - not necessarily surjective, and is many-to-one (by def.)
- scatter - one-to-many (by def.) and is not necessarily surjective
- stencil - several-to-one (not injective, by definition), and is surjective
- reduce - all-to-one
- scan/sort - all-to-all

Programmer View of the GPU

thread blocks: group of threads that cooperate to solve a (sub)problem

Thread Blocks And GPU Hardware

CUDA GPU is a bunch of SMs:

Streaming Multiprocessors (SM)s

SMs have a bunch of simple processors and memory.

Dr. Luebki:

> Let me say that again because it's really important
> GPU is responsible for allocating blocks to SMs

Programmer only gives GPU a pile of blocks.

Quiz: What Can The Programmer Specify

I myself thought this was a revelation and was not intuitive at first:

Given a single kernel that's launched on many thread blocks include X, Y, the programmer cannot specify the sequence the blocks, e.g. block X, block Y, run (same time, or run one after the other), and which SM the block will run on (GPU does all this).

Quiz: A Thread Block Programming Example

Open up `hello blockIdx.cu` in Lesson 2 Code Snippets (I got the repository from github, repo name is cs344).

At first, I thought you can do a single file compile and run in Eclipse without creating a new project. No. cf. Eclipse creating projects every time to run a single file?.

I ended up creating a new CUDA C/C++ project from File -¿ New project, and then chose project type Executable, Empty Project, making sure to include Toolchain CUDA Toolkit (my version is 7.5), and chose an arbitrary project name (I chose cs344single). Then, as suggested by Kenny Nguyen, I dragged and dropped files into the folder, from my file directory program.

I ran the program with the "Play" triangle button, clicking on the green triangle button, and it ran as expected. I also turned off Build Automatically by deselecting the option (no checkmark).

GPU Memory Model

$$\text{thread} \xleftarrow[\text{read}]{} \text{local memory} \circlearrowright \text{write}$$

Then consider threadblock $\equiv$ thread block

Objthreadblock $\supset$ { threads }

FinSet $\xrightarrow{\text{threadIdx}}$ thread $\in$ Morthreadblock

$$\text{threadblock} \xleftarrow[\text{read}]{} \text{shared memory} \circlearrowright \text{write}$$

$\forall$ thread,

$$\text{thread} \xleftarrow[\text{read}]{} \text{global memory} \circlearrowright \text{write}$$

Synchronization - Barrier

Quiz: The Need For Barriers

3 barriers were needed (wasn't obvious to me at first). All threads need to finish the write, or initialization, so it'll need a barrier.

While

```
array[idx] = array[idx+1];
```

is 1 line, it'll actually need 2 barriers; first read. Then write.

So *actually* we'll need to *rewrite* this code:

```
int temp = array[idx+1];
__syncthreads();
array[idx] = temp;
__syncthreads();
```

kernels have implicit barrier for each.

Writing Efficient Programs

(1) Maximize *arithmetic intensity* arithmetic intensity := $\frac{\text{math}}{\text{memory}}$

video: Minimize Time Spent On Memory

local memory is fastest; global memory is slower

$$\text{local} > \text{shared} >> \text{global} >> \text{CPU}$$

kernel we know (in the code) is tagged with `__global__`

quiz: A Quiz on Coalescing Memory Access

Work it out as Dr. Luebki did to figure out if it's coalesced memory access or not.

Atomic Memory Operations

Atomic Memory Operations

atomicadd atomicmin atomicXOR atomicCAS Compare And Swap

4. Pointers in C; Pointers in C categorified (interpreted in Category Theory)

Suppose $v \in$ ObjData, category of data **Data**,

e.g. $v \in$ Int $\in$ ObjType, category of types Type.

$$\text{Data} \xrightarrow{\&} \text{Memory}$$

$$v \xmapsto{\&} \&v$$

with address $\&v \in$ Memory.

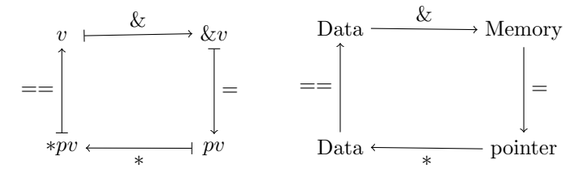
With

assignment $pv = \&v$,

$pv \in$ Objpointer, category of pointers, pointer

$pv \in$ Memory (i.e. not $pv \in$ Dat, i.e. $pv \notin$ Dat)

$$\text{pointer} \ni pv \xmapsto{*} *pv \in \text{Dat}$$



Examples. Consider `passfunction.c` in Fitzpatrick [5].

Consider the type `double`, `double` $\in$ ObjTypes.

fun1, fun2 $\in$ MorTypes namely

fun1, fun2 $\in \text{Hom}(\text{double}, \text{double}) \equiv \text{Hom}_{\text{Types}}(\text{double}, \text{double})$

Recall that

$$\text{pointer} \xrightarrow{*} \text{Dat}$$

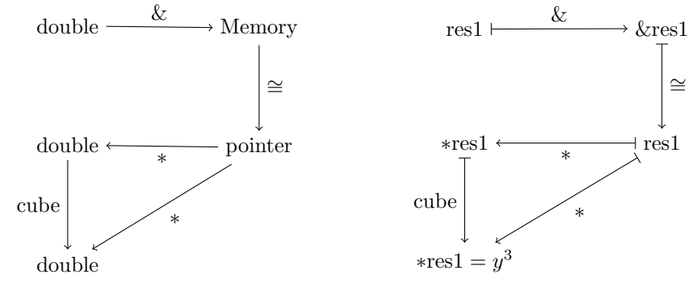
$$\text{pointer} \xrightarrow{\&} \text{Memory}$$

$*, \&$ are functors with domain on the category pointer.

Pointers to functions is the "extension" of functor $*$ to the codomain of MorTypes:

$$\text{pointer} \xrightarrow{*} \text{MorTypes}$$

$$\text{fun1} \xmapsto{*} *\text{fun1} \in \text{Hom}_{\text{Types}}(\text{double}, \text{double})$$



It's unclear to me how `void cube` can be represented in terms of category theory, as surely it cannot be represented as a mapping (it acts upon a functor, namely the $*$ functor for pointers). It doesn't return a value, and so one cannot be confident to say there's explicitly a domain and codomain, or range for that matter.

But what is going on is that

$$\text{pointer , double , pointer} \xrightarrow{\text{cube}} \text{pointer , pointer}$$

$$\text{fun1}, x, \text{res1} \overset{\text{cube}}{\mapsto} \text{fun1}, \text{res1}$$

s.t. $*\text{res1} = y^3 = (*\text{fun1}(x))^3$

So I'll speculate that in this case, `cube` is a functor, and in particular, is acting on $*$, the so-called deferencing operator:

$$\begin{array}{c} \text{pointer} \xrightarrow{*} \text{float} \in \text{Data} \\ \text{res1} \overset{*}{\mapsto} *\text{res1} \end{array} \xrightarrow{\text{cube}} \begin{array}{c} \text{pointer} \xrightarrow{\text{cube}(*)} \text{float} \in \text{Data} \\ \text{res1} \overset{\text{cube}(*)}{\mapsto} \text{cube}(*\text{res1}) = y^3 \end{array}$$

cf. Arrays, from Fitzpatrick [5]

$$\text{Types} \xrightarrow{\text{declaration}} \text{arrays}$$

If $x \in$ Objarrays,

$$\&x[0] \in \text{Memory} \xrightarrow{==} x \in \text{ pointer (to 1st element of array)}$$

cf. Section 2.13 Character Strings from Fitzpatrick [5]

```
char word[20] = ''four''
char *word = ''four''
```

cf. C++ extensions for C according to Fitzpatrick [5]

- simplified syntax to pass by reference pointers into functions
- inline functions
- variable size arrays

```
int n;
double x[n];
```

- complex number class

4.0.7. *Need a CUDA, C, C++, IDE? Try Eclipse!* This website has a clear, lucid, and pedagogical tutorial for using Eclipse: Creating Your First C++ Program in Eclipse. But it looks like I had to pay. Other than the well-written tips on the webpage, I looked up stackexchange for my Eclipse questions (I had difficulty with the Eclipse documentation).

Part 3. Machine Learning with Deep Learning

cf. Machine Learning - Introduction, from Coursera. Dr. Andrew Ng.

(1) Week 1

- Linear Regression with One Variable
  - Model and Cost Function
    - Model Representation
    - Cost Function
    - Cost Function - Intuition I
    - Cost Function - Intuition II
  - Parameter Learning
    - Gradient Descent
    - Gradient Descent Intuition
    - Gradient Descent For Linear Regression

cf. Linear Regression with One Variable

cf. Model Representation; Week 1 Linear Regression with 1 Variable, Coursera Machine Learning, Ng

For hypothesis h,

$$h_\theta : \mathbb{R}^d \to \mathbb{R}$$
$$h_\theta : x \mapsto h_\theta(x) \qquad \text{(prediction of } y \text{ for } x)$$

$h_\theta \in L(\mathbb{R}^d, \mathbb{R})$

$$h_\theta : \mathbb{R}^{|\theta|} \to L(\mathbb{R}^d, \mathbb{R})$$
$$\theta \mapsto h_\theta$$

Cost Function; Week 1, Coursera, Machine Learning, Ng

So for parameters

$$\theta \in \mathbb{R}^{|\theta|}$$

define a *cost function*

$$J(\theta) = \frac{1}{2m}\sum_{i=1}^{m}(h_\theta(x_i) - y_i)^2 \tag{1}$$

Find

$$\min_\theta J(\theta) = ?(???)$$

for

$$J : \mathbb{R}^{|\theta|} \to \mathbb{R}$$

Actually,

$$J(\theta, (x_i, y_i)_{i \in I_{\text{train}}})$$
$$J : \mathbb{R}^{|\theta|} \times (\mathbb{R}^d)^m \times \mathbb{R}^m \to \mathbb{R} \tag{2}$$

$m =$ number of training examples $= |I_{\text{train}}|$.

Considering

$$H(\theta + \Delta\theta) \approx J(\theta) + \text{grad}J(\theta) \cdot \Delta\theta + \frac{1}{2t}\|\Delta\theta\|^2$$

Suppose $\Delta\theta \equiv \Delta\theta(t) = t\Delta\theta$

$\Delta\theta \approx -\gamma \text{grad}J(\theta)$ is an ansatz, γ small enough.

Then assume J convex, use this ansatz by plugging in, with Lipshitz condition

$$\|\text{grad}J(\theta + \Delta\theta) - \text{grad}J(\theta)\| \leq L\|\Delta\theta\|$$

some constant $L > 0$,

$$\begin{aligned} \theta_{n+1}^i &= \theta_n^i - \gamma_n(\text{grad}J(\theta))^i \\ \gamma_n &= \frac{(\theta_n^i - \theta_{n-1}^i)(\text{grad}_\theta J(x_n) - \text{grad}_\theta J(x_{n-1}))^i}{\|\text{grad}_\theta J(x_n) - \text{grad}_\theta J(x_{n-1})\|^2} = \frac{(\theta_n - \theta_{n-1}) \cdot (\text{grad}_\theta J(x_n) - \text{grad}_\theta J(x_{n-1}))}{\|\text{grad}_\theta J(x_n) - \text{grad}_\theta J(x_{n-1})\|^2} \end{aligned} \tag{3}$$

or as Ng points out in the Gradient Descent lesson recap, the correct way is to store in temporary variables first:

$$\begin{aligned} \text{temp} &= \theta_n^i - \gamma_n(\text{grad}J(\theta))^i \\ \theta_{n+1}^i &= \text{temp} \end{aligned} \tag{4}$$

where temp $\in \mathbb{R}^{|\theta|}$

In the lesson recap for Gradient Descent Intuition, Ng denotes the learning rate $\alpha \in \mathbb{R}$ with α, but note that it's denoted as γ or `gamma` for `sci-kit learn`. So be aware of different notations. Nevertheless, the learning rate can be a constant, but even then, choosing it is nontrivial.

4.0.8. *Testing many hypotheses at the same time, via refactoring the matrix.* In Linear Algebra Review of Week 1, Matrix Matrix Multiplication, Ng provided a useful tip in refactoring the matrix of hypotheses h_θ so to test multiple number of hypotheses at the same time on the same input data, X.

Mathematically, beginning with

$$h : \mathbb{R}^{|\theta|} \longrightarrow L(\mathbb{R}^d, \mathbb{R})$$

$$\theta \longmapsto h_\theta$$

Consider testing H different hypotheses, $\underbrace{\mathbb{R}^{|\theta|} \times \cdots \times \mathbb{R}^{|\theta|}}_{H} \equiv \otimes_{i=1}^{H} \mathbb{R}^{|\theta|}$,

so treat

$$\otimes_{i=1}^{H} \mathbb{R}^{|\theta|} = \mathrm{Mat}_{\mathbb{R}}(|\theta|, H)$$

and so

$$h : \otimes_{i=1}^{H} \mathbb{R}^{|\theta|} = \mathrm{Mat}_{\mathbb{R}}(|\theta|, H) \longrightarrow \otimes_{i=1}^{H} L(\mathbb{R}^d, \mathbb{R})$$

$$\theta^{(i)} \longmapsto h_{\theta^{(i)}}$$

cf. Week 4, Non-linear Hypotheses video of Motivations for Coursera's Machine Learning by Ng

For a sigmoid function g, consider

$$g(\theta_0 + \theta_1 x_1 + \theta_2 x_2 + \theta_3 x_1 x_2 + \theta_4 x_1^2 x_2 + \theta_5 x_1^3 x_2 + \theta_6 x_1 x_2^2 + \dots)$$

If n large (Ng's notation), $d = \dim\mathbb{R}^d$, number of features for training (data) set,
for including quadratic features,

$$x_1^2, x_1x_2, x_1x_3, x_1x_4 \dots x_1x_{100}$$
$$x_2^2, x_1x_3, \dots$$
$$\approx \mathcal{O}(n^2) \approx \frac{n^2}{2} \qquad (\mathcal{O}(d^2) \approx \frac{d^2}{2})$$

e.g. computer vision,
e.g. 50×50 pixel images,
$n = 2500$
pixel intensity $\in [0, 255]$
rgb $\in [0, 255]^3$

$$g : \mathbb{R}^{|\theta|} \to L(\mathbb{R}^d, \mathbb{R})$$
$$\theta \mapsto g(\theta) \equiv g_\theta$$

$n \equiv d = 2$.

Consider

$$\sum_{\substack{a_1, a_2 = 0 \\ i = a_1 + 2a_2}} \theta^{(i)} x_1^{a_1} x_2^{a_2}$$

and so for this example

$$g(\theta)(x_1, x_2) = g\left(\sum_{\substack{a_1, a_2 = 0 \\ i = a_1 + 2a_2}} \theta^{(i)} x_1^{a_1} x_2^{a_2} \right)$$

For computer vision, consider

$$x \in \mathbb{R}^d \text{ with } d = n^x \times n^y$$

and in particular, given pixel intensity or rgb range,

$$x \in [0, 255]^d$$
$$x \in [0, 255]^{3d}$$

cf. Model Representation I of Week 4, Coursera's Machine Learning Introduction with Ng
The notes at the end of each video segment **help very much**.
For input

$$\mathbf{x} \in \mathbb{R}^d$$

e.g. $d = 1, 2, 3,$ or $4, \dots$
$x_0 =$ "bias unit", input node 0, $x_0 = 1$ always (Ng).
Sigmoid (logistic) activation function $\equiv a$.

$$a_i^{(j)} \equiv \text{ "activation" of unit } i \text{ in layer } j$$

$j \in \{2, \dots, N-1\}$, $j = 1$ is input layer, $j = N$ is output layer.

$$a_i^{(j)} = g(\Theta_{ik}^{(j-1)} x_k)$$

$$j \xrightarrow{\Theta^{(j)}} j + 1$$

$\Theta^{(j)}$ matrix of weights controlling function mapping from layer j to layer $j + 1$.

$$h_\Theta(x) = a_1^{(N)} = g(\Theta_{1k}^{(N-1)} a_k^{(N-1)})$$

$\forall$ layer j, $\exists$ matrix of weights $\Theta^{(j)}$.
If s_j units in layer j, s_{j+1} units in layer $j + 1$, $\dim\Theta^{(j)} = s_{j+1} \times (s_j + 1)$
If $N = 2$, (1 neuron or only 1 hidden layer)

$$x = (x_i)_{i=1\dots d} \in \mathbb{R}^d, \qquad y \in \mathbb{R},\ x_0 = 1$$
$$y = h(\Theta_{1k}^{(1)} x_k^{(1)}) = h(\Theta_{1k}^{(1)} x_k) = h(\Theta^{(1)})(x)$$

e.g. $h(z) = \frac{1}{1+e^z}$ logistic function.

Neural Network, input layer, output layer, and hidden layers.

$$\Theta_{ik}^{(j)} x_k \mapsto g a_i^{(j+1)} \qquad \begin{matrix} k = 0, 1, \dots s_j \\ i = 1, 2, \dots s_{j+1} \end{matrix} \tag{5}$$

Note that y can be $y \in \mathbb{R}^M$, not just $M = 1$.
Model Representation II
$z_i^{(j)}$, $i = 1, \dots s_j$, layer $j = 1, \dots N$.

$$g : z_i^{(j)} \mapsto a_i^{(j)} \tag{6}$$

e.g. $z_i^{(j)} = \Theta_{ik}^{(j-1)} x_k$, $k = 0, 1 \dots d$.
Set $x = a^{(1)}$ for input layer.

$$\Theta^{(j-1)} \in \mathrm{Mat}_{\mathbb{R}}((d+1), s_j)$$
$$\Theta^{(j-1)} : a^{(j-1)} \in \mathbb{R}^{d+1} \mapsto z^{(j)} \in \mathbb{R}^{s_j} \xrightarrow{g} a^{(j)} \in \mathbb{R}^{s_j} \xrightarrow{a_0^{(j)} = 1} a^{(j)} \in \mathbb{R}^{s_j + 1} \tag{7}$$

For the $j = N$ case, "output" layer,

$$\Theta^{(N-1)} : a^{(N-1)} \mapsto z^N \in \mathbb{R} \xrightarrow{g} g(z^N) = a^N = h_\Theta(x) \in \mathbb{R} \qquad \Theta^{(N-1)} \in \mathrm{Mat}_{\mathbb{R}}(s_{N-1}+1, 1) \tag{8}$$

In general,

$$\Theta^{(N-1)} : a^{(N-1)} \mapsto z^N \in \mathbb{R} \xrightarrow{g} g(z^N) = a^N = h_\Theta(x) \in \mathbb{R}^M \qquad \Theta^{(N-1)} \in \mathrm{Mat}_{\mathbb{R}}(s_{N-1}+1, M)$$

cf. Learning With Large Datasets, Quiz of Week 10, Gradient Descent with Large Datasets; Learning with Large Datasets.

Suppose you are facing a supervised learning problem and have a very large dataset ($m = 100,000,000$). How can you tell if using all of the data is likely to perform much better than using a small subset of the data (say $m = 1,000$)?

Plot a learning curve ($J_{\text{train}}(\theta)$ and $J_{CV}(\theta)$, plotted as a function of m) for a range of values of m and verify that the algorithm has high variance when m is small.

cf. 1.4 Regularized cost function

$$J(\theta) = \frac{1}{m}\sum_{i=1}^{m}\sum_{k=1}^{K}\left[-y_k^{(i)}\log\left((h_\theta(x^{(i)}))_k\right) - (1-y_k^{(i)})\log\left(1-(h_\theta(x^{(i)}))_k\right)\right] + \\ + \frac{\lambda}{2m}\left[\sum_{j=1}^{s_2}\sum_{k=1}^{d}(\Theta_{j,k}^{(1)})^2 + \sum_{j=1}^{K}\sum_{k=1}^{s_2}(\Theta_{j,k}^{(2)})^2\right]$$

5. Feedforward; Feedforward Propagation and Prediction

Given ordered sequence of linear transformations L, $L \geq 2$,

$$\Theta^{(l)} \in \mathrm{Mat}_{\mathbb{R}}(s_l+1, s_{l+1}) \text{ i.e. } s_{l+1} \times (s_l+1) \text{ matrix size }, \forall l = 1, 2, \dots L-1 \\ \Theta^{(l)} : \mathbb{R}^{s_l+1} \to \mathbb{R}^{s_{l+1}} \\ \Theta^{(l)} : a^{(l)} \mapsto z^{(l+1)} = \Theta^{(l)}a^{(l)} = \Theta_{ij}^{(l)}a_j^{(l)} = z_i^{(l+1)} \tag{9}$$

$a^{(l)} \equiv$ "activation" of layer l.

$s_l \equiv$ "layer size" of layer l, number of units or nodes in layer l

$$g : \mathbb{R}^{s_l} \to \mathbb{R}^{s_l} \\ g : z^{(l)} \mapsto g(z^{(l)}) \tag{10}$$

e.g. g sigmoid function.

Remember to add $a_0^{(l)} = 1$, $\forall l = 1, \dots L-1$, i.e. $\forall$ input layer and hidden layers.

For $l = 1$, the so-called *input layer*, is such that

$$(a_0^{(1)} = 1, x) = a^{(1)} \tag{11}$$

For $l = 1, 2, \dots L-1$,

$$\mathbb{R}^{s_l} \xrightarrow{a_0^{(l)}=1} \mathbb{R}^{s_l+1} \xrightarrow{\Theta^{(l)}} \mathbb{R}^{s_{l+1}} \xrightarrow{g} \mathbb{R}^{s_{l+1}}$$

$$a^{(l)} \xmapsto{a_0^{(l)}=1} (a_0^{(l)} = 1, a^{(l)}) \xmapsto{\Theta^{(l)}} z^{(l+1)} \xmapsto{g} g(z^{(l+1)}) = a^{(l+1)} \tag{12}$$

6. Backpropagation; Backpropagation algorithm

First, do feedforward on *each* training example t, i.e.

$$\forall t = 1, 2 \dots m$$

$$\mathbb{R}^d \xrightarrow{(g\circ\Theta^{(l)}\circ(a_0^{(l)}=1)\times\cdot)^{L-1}} \mathbb{R}^K \\ x^{(t)} \xmapsto{(g\circ\Theta^{(l)}\circ(a_0^{(l)}=1)\times\cdot)^{L-1}} a^{(L)} \tag{13}$$

For $K = 1$ or $K > 1$ e.g. $K = 10$ for multi-class logistic regression.

In fact, we obtain an ordered sequence of "activation" vectors:

$$\forall t = 1, 2 \dots m$$

$$\mathbb{R}^d \xrightarrow{(g\circ\Theta^{(l)}\circ(a_0^{(l)}=1)\times\cdot)^{L-1}} \mathbb{R}^{s_2} \times \mathbb{R}^{s_2} \times \mathbb{R}^{s_3} \times \mathbb{R}^{s_3} \times \cdots \times \mathbb{R}^K \\ x^{(t)} \xmapsto{(g\circ\Theta^{(l)}\circ(a_0^{(l)}=1)\times\cdot)^{L-1}} z^{(2)}, a^{(2)}, z^{(3)}, a^{(3)}, \dots, a^{(L)} \tag{14}$$

From Backpropagation algorithm, Cost Function and Backpropagation, Week 5 of Coursera's Machine Learning Introduction by Ng, Backpropagation algorithm notes, and `ex4.pdf`

Calculate

$$\delta^{(L)} := a^{(L)} - y \\ \delta_k^{(L)} := a_k^{(L)} - y_k \qquad \forall k = 1, 2, \dots K \tag{15}$$

For the term $((\Theta^{(L-1)})^T\delta^{(L)})$, the matrix size dimensions of the $(\Theta^{(L-1)})^T$ are $\dim(\Theta^{(L-1)})^T = (s_{L-1}+1) \times s_L$.

It seems that the element-wise or component-wise multiplication that seems obvious in Matlab/Octave or numpy is called the *Hadamard product*, denoted $\circ$ or $\odot$. There ought to be a homomorphism that maps this operation onto "vectorized" forms of these vectors that allows for, or is equipped with the operation, Hadamard product.

For $m = 1$,

$$\delta^{(L-1)} := \left((\Theta^{(L-1)})^T\delta^{(L)}\right) \odot g'(z^{(L-1)}) \in \mathbb{R}^{s_{L-1}+1} \qquad \forall k = 0, 1, \dots s_{L-1}$$

i.e.

$$\mathrm{vec}(\delta^{(L-1)}) = \mathrm{vec}((\Theta^{(L-1)})^T\delta^{(L)}) \odot \mathrm{vec}(g'(z^{(L-1)})) \mapsto \delta^{(L-1)} \in \mathbb{R}^{s_{L-1}+1} \\ (s^{(L-1)})_K := ((\Theta^{(L-1)})^T\delta^{(L)})_K(g'(z^{(L-1)}))_K$$

Then add this term to the so-called "accumulator matrix" $\Delta^{(l)}$:

$$\Delta^{(l)} := \Delta^{(l)} + \delta^{(l+1)}(a^{(l)})^T$$

Note that prior, skip or *remove* $\delta_0^{(l+1)}$ entry:

$$\delta^{(l+1)} \in \mathbb{R}^{s_{l+1}+1} \xrightarrow{r} \delta^{(l+1)} \in \mathbb{R}^{s_{l+1}}$$

The whole purpose is to obtain

$$\frac{\partial}{\partial\Theta_{ij}^{(l)}}J(\Theta) = a_j^{(l)}\delta_i^{(l+1)} = a_j^{(l)}((\Theta^{(l+1)})^T\delta^{(l+2)} \odot g'(z^{(l+1)}))_i$$

which can be shown.

So first we had set

$$\Delta_{ij}^{(l)} = 0$$

for

$$\Delta^{(l)} \in \mathrm{Mat}_{\mathbb{R}}(s_l, s_{l+1}) \in \mathbb{R}^{s_l} \otimes \mathbb{R}^{s_{l+1}}$$

Again, it can be shown that

$$\Delta_{ij}^{(l)} = \frac{\partial}{\partial \Theta_{ij}^{(l)}} J(\Theta) \tag{16}$$

and so

$$\Delta^{(l)} := \Delta^{(l)} + \delta^{(l+1)}(a^{(l)})^T$$
$$\Delta_{ij}^{(l)} := \Delta_{ij}^{(l)} + \delta_j^{(l+1)}(a^{(l)})_i$$

and so for $\forall\, t$,

$$\begin{cases} D_{ij}^{(l)} := \frac{1}{m}\Delta_{ij}^{(l)} + \lambda\Theta_{ij}^{(l)} & \text{if } j \neq 0 \\ D_{ij}^{(l)} := \frac{1}{m}\Delta_{ij}^{(l)} & \text{if } j = 0 \end{cases}$$
$$D^{(l)} = \frac{1}{m}\sum_{t=1}^{m}(\Delta^{(l)})^{(t)} + \lambda\Theta^{(l)} \in \mathrm{Mat}_{\mathbb{R}}(s_l, s_{l+1})$$

In summary, we have, for the first step,

$$\delta^{(L)} := a^{(L)} - y \in \mathbb{R}^K \tag{17}$$

$$\delta^{(l)} = (\Theta^{(l)})^T\delta^{(l+1)} \odot g'(z^{(l)}) \in \mathbb{R}^{s_l+1}, \qquad l = L-1, L-2, \dots 2, \qquad (L-2) \text{ steps} \tag{18}$$

and so for

$$(\Delta^{(l)})^{(t)} := (\delta^{(l+1)}(a^{(l)})^T)^{(t)} \tag{19}$$

$$D^{(l)} = \frac{1}{m}\sum_{t=1}^{m}(\Delta^{(l)})^{(t)} + \lambda\Theta^{(l)} \in \mathrm{Mat}_{\mathbb{R}}^{l}(s_l, s_{l+1}) \tag{20}$$

with $D^{(l)} \sim \frac{\partial}{\partial\Theta_{ij}^{(l)}}J(\Theta)$.

And so

$$(\mathbb{R}^{s_2})^2 \times (\mathbb{R}^{s_3})^2 \times \cdots \times (\mathbb{R}^K)^2 \longrightarrow \mathrm{Mat}_{\mathbb{R}}(s_1, s_s) \times \mathrm{Mat}_{\mathbb{R}}(s_2, s_3) \times \cdots \times \mathrm{Mat}_{\mathbb{R}}(s_{L-1}, s_L)$$

$$z^{(2)}, a^{(2)}, z^{(3)}, a^{(3)}, \dots, z^{(L)}, a^{(L)} \longmapsto (\Delta^{(1)})^{(t)}, (\Delta^{(2)})^{(t)}, \dots, (\Delta^{(L-1)})^{(t)} \tag{21}$$

$\forall\, t = 1, \dots m$, then obtaining

$$D^{(l)} \sim \frac{\partial}{\partial\Theta_{ij}^{(l)}}J(\Theta) \in \mathrm{Mat}_{\mathbb{R}}(s_l, s_{l+1}) \qquad \forall\, l = 1, 2, \dots L-1 \tag{22}$$

To collect our facts, consider that we're given $x \in (\mathbb{R}^d)^m$, with $x_i^{(t)}$, $i = 1 \dots d$, with $t = 1 \dots m$ and $y \in (\mathbb{R}^K)^m$ / $y \in \{1, 2, \dots K\}^m$ (classifier).

"layer" $l = 1, 2, \dots L-1$ For input layer $\Theta^{(1)} : \mathbb{R}^{d+1} \to \mathbb{R}^{s_2}$, $\Theta^{(1)} : a^{(1)} \mapsto \Theta^{(1)}a^{(1)} = z^{(1)}$, with $a^{(1)} = (1, x^{(t)})$.

Instead of thinking of separate "layers", one should really think of encapsulating the relation, or arrows, or mappings between "layers":

$$\mathbb{R}^d \xrightarrow{a_0^{(1)}=1} \mathbb{R}^{d+1} \xrightarrow{\Theta^{(1)}} \mathbb{R}^{s_2} \xrightarrow{g} \mathbb{R}^{s_2}$$

$$x \xmapsto{a_0^{(1)}=1} (a_0^{(l)} = 1, x) \xmapsto{\Theta^{(1)}} z^{(2)} \xmapsto{g} g(z^{(2)}) = a^{(2)} \tag{23}$$

$$\mathbb{R}^{s_l} \xrightarrow{a_0^{(l)}=1} \mathbb{R}^{s_l+1} \xrightarrow{\Theta^{(l)}} \mathbb{R}^{s_{l+1}} \xrightarrow{g} \mathbb{R}^{s_{l+1}}$$

$$a^{(l)} \xmapsto{a_0^{(l)}=1} (a_0^{(l)} = 1, a^{(l)}) \xmapsto{\Theta^{(l)}} z^{(l+1)} \xmapsto{g} g(z^{(l+1)}) = a^{(l+1)} \tag{24}$$

I found that Theano wasn't like the '`.stack`' method, the "addition" of adding the $a_0 = 1$ component to a vector or matrix, as a shared variable, very much on the GPU (it indeed is a bug, Merge fails on GPU but passes on CPU #152 , and so I rewrote the mathematical formulation to fit in with separating the intercepts from the "weights" or Θ.

For

$$\Theta^{(l)}, b^{(l)} : \mathbb{R}^{s_l} \to \mathbb{R}^{s_l+1} \tag{25}$$

where

$$\Theta^{(l)} \in \mathrm{Mat}_{\mathbb{R}}(s_l, s_{l+1}) = \mathbb{R}^{s_{l+1}} \otimes (\mathbb{R}^{s_l})^*$$
$$b^{(l)} \in \mathbb{R}^{s_{l+1}} \tag{26}$$

$$\mathbb{R}^{s_l} \xrightarrow{\Theta^{(l)}, b^{(l)}} \mathbb{R}^{s_{l+1}} \xrightarrow{g} \mathbb{R}^{s_{l+1}}$$

$$a^{(l)} \xmapsto{\Theta^{(l)}, b^{(l)}} z^{(l+1)} \xmapsto{g} g(z^{(l+1)}) = a^{(l+1)} \tag{27}$$

6.1. **Cost functional.** The cost function J is really a cost *functional*, to first input in the output values y. So

$$J : (\mathbb{R}^K)^m \to L((\mathbf{\Theta}, \mathbf{b}), \mathbb{R})$$
$$J : y \mapsto J_y \equiv J \tag{28}$$

for a "vector-valued" regression, with the usual linear regression being the case of $K = 1$.

For y taking on discrete values,

$$J : \{1, 2, \dots K\}^m \to L((\mathbf{\Theta}, \mathbf{b}), \mathbb{R})$$
$$J : y \mapsto J_y \equiv J \tag{29}$$

Then, we can find the cost $J((\Theta, b))$, for a particular choice of the parameters, $(\Theta, b) \in (\mathbf{\Theta}, \mathbf{b})$:

$$J_y \equiv J : (\mathbf{\Theta}, \mathbf{b}) \to \mathbb{R}$$
$$J : (\Theta, b) \to J(\Theta, b) \tag{30}$$

i.e. $J \in C^\infty((\Theta, b))$ (hopefully J is smooth or at least C^2 differentiable, so that a Hessian can be obtained).

For the above $(\mathbf{\Theta}, \mathbf{b})$ was notation or shorthand as follows:

$$(\mathbf{\Theta}, \mathbf{b}) \equiv (\mathrm{Mat}_{\mathbb{R}}(s_1, s_2) \times \mathbb{R}^{s_2}) \times (\mathrm{Mat}_{\mathbb{R}}(s_2, s_3) \times \mathbb{R}^{s_3}) \times \cdots \times (\mathrm{Mat}_{\mathbb{R}}(s_{L-1}, s_L) \times \mathbb{R}^{s_L})$$

7. Universal approximation theorem

Wikipedia: Universal Approximation Theorem

From Hornik (1991) [7], pp. 252, Section 2. Results,

$$\mathcal{N}_k^{(n)}(\psi) = \{h : \mathbb{R}^k \to \mathbb{R} | h(x) = \sum_{j=1}^{n} \beta_j \psi(a_j' x - \theta_j)\} \tag{31}$$

with $\begin{matrix} a = (\alpha_1, \dots \alpha_k) \\ x = (\xi_1, \dots, \xi_k) \end{matrix}$ with $a' \equiv a^T \equiv$ transpose of a.

For arbitrary number of hidden layers,

$$\mathcal{N}_k(\psi) = \bigcup_{n=1}^{\infty} \mathcal{N}_k^{(n)}(\psi)$$

The 2 very important theorems from Hornik (1991) are the following:

Theorem 1. *If ψ unbounded and nonconstant, then $\mathcal{N}_k(\psi)$ dense in $L^p(\mu)$, $\forall$ finite measure μ on $\mathbb{R}^k$*

Theorem 2. *If ψ cont., bounded, nonconstant, then $\mathcal{N}_k(\psi)$ dense in $C(X)$, $\forall$ compact subsets X of $\mathbb{R}^k$, i.e. $\forall f \in C(X)$, $\exists$ sequence, (h_n) s.t. $h_n \overset{n}{\to} f$ uniformly i.e. $\forall$ given $\epsilon > 0$, $\exists N = N(\epsilon)$ (independent of $x \in X \subset \mathbb{R}^k$), s.t. $|h_n(x) - f(x)| < \epsilon \quad \forall x \in X, \quad \forall n \geq N(\epsilon)$*

I will write now a dictionary between Hornik's notation and my notation (take note, Hornik's notation $\equiv$ my notation).
$f \in C(X)$, $f : \mathbb{R}^k \to \mathbb{R}$, $k \equiv d$, so $f : \mathbb{R}^d \to \mathbb{R}$

$\psi \equiv g$, e.g. $g(z) = \frac{1}{1+\exp(-z)}$ or $g(z) = \tanh(z)$, but equip g with element-wise (component-wise) action, i.e. g as a functor,

$g : \mathbb{R}^k \to \mathbb{R}^k$, i.e. $g : \mathbf{Vec} \to \mathbf{Vec}$.

$g : x_j \mapsto g(x_j)$

Now $a \equiv \Theta \in \mathrm{Mat}_{\mathbb{R}}(d, n)$,

$$g(\Theta x + b) = g(z)$$

i.e. $z \in \mathbb{R}^n$,

$$z := \Theta x + b \text{ i.e. } z_j = \Theta_{jk} x_k + b_j \qquad g(z) \in \mathbb{R}^n$$

and so, notation-wise,

$$\sum_{j=1}^{n} \beta_j \psi(a_j' x - \theta_j) \equiv \sum_{j=1}^{n} \beta_j g(\Theta_{jk} x_k + b_j)$$

Consider

$$\Theta^{(1)} \in \mathrm{Mat}_{\mathbb{R}}(d, s_2),\ b^{(1)} \in \mathbb{R}^{s_2}$$
$$\Theta^{(2)} \in \mathrm{Mat}_{\mathbb{R}}(s_2, 1),\ b^{(2)} \in \mathbb{R}$$
$$h(x) = \Theta^{(2)} g(\Theta^{(1)} x + b^{(1)}) + b^{(2)} \in \mathcal{N}_d^{(s_2)}(g)$$

so the neural net of L total layers $d = 1$ "input layer", $l = L$ is "output layer" is a tuple $((\Theta, b), g) \in \mathcal{N}_d^{(L)}(g)$

Hornik, Stinchcombe, and White (1989) [8] deals with multi-(hidden) layer networks on pp. 363, on and after Corollary 2.6.

Given training data,

$$\begin{aligned} (X, y) &: \mathbb{R} \to (\mathbb{R}^d \times \mathbb{R}^k)^m \\ (X, y)(t) &\mapsto (X(t), y(t)) \end{aligned} \tag{32}$$

discretize time $t \in \mathbb{R}$,

$$\begin{aligned} \mathbb{R} &\xrightarrow{\text{discretize}} \mathbb{Z} \\ [0, T] \text{ where } T \in \mathbb{R}^+ &\to \{0, 1, \dots T-1\} \text{ where } T \in \mathbb{Z}^+ \end{aligned} \tag{33}$$

Consider 4 different feedforwards. Note $y(-1) = 0$.

8. LSTM; Long Short Term Memory

LSTM (Long Short Term Memory), according to Christian Herta

Rewriting Herta's formulation of LSTM, which actually puts in the "cell" memory into some of the input, forget gates, that's different from a "traditional" LSTM (see Wikipedia),

$$\begin{aligned} \text{input gates } i_t &= \psi_{(i)}(\Theta^{(i)} X_t + b^{(i)} + \theta^{(i)} h_{t-1} + W^{(i)} c_{t-1}) \\ f_t &= \psi_{(f)}(\Theta^{(f)} X_t + b^{(f)} + \theta^{(f)} h_{t-1} + W^{(f)} c_{t-1}) \\ c_t &:= f_t \odot c_{t-1} + i_t \odot g_t \\ \text{output gates } o_t &= \psi_{(0)}(\Theta^{(0)} X_t + b^{(0)} + \Theta^{(0)} g_{t-1} + W^{(0)} c_t) \end{aligned} \tag{34}$$

and then finally, not predict yet (I was mistaken) but h here denotes some other "hidden" variable,

$$h_t = o_t \odot \psi_h(c_t) \tag{35}$$

$o_t, c_t \in \mathbb{R}^H$, and so $W^{(i)}, W^{(f)}, W^{(0)} \in \mathrm{Mat}_{\mathbb{R}}(H, s_2)$.

$$\begin{aligned} y_t &= \psi_{(y)}(\Theta^{(y)} h_t + b^{(y)}) \\ \Theta^{(y)} &: \mathbb{R}^{s_L} \to \mathbb{R}^K \end{aligned} \tag{36}$$

$$(\mathbb{R}^d \times \mathbb{R}^H)^m \times (\mathbb{R}^H) \xrightarrow{\{\psi_\alpha \circ ((\Theta^{(\alpha)}, b^{(\alpha)}), \theta^{(\alpha)}, W^{(\alpha)})\}_{\alpha = i, f, g}} (\mathbb{R}^H \times \mathbb{R}^H \times \mathbb{R}^H)^m \longrightarrow (\mathbb{R}^H \times \mathbb{R}^H)^m \longrightarrow (\mathbb{R}^H)^m \tag{37}$$

$$X_t, h_{t-1}, c_{t-1} \longmapsto (i_t, f_t, g_t) \longmapsto c_t, o_t \longmapsto h_t$$

Consider what we're essentially doing at time step t:

$$((\mathbb{R}^d \times \mathbb{R}^H) \times (\mathbb{R}^H))^m \xrightarrow{\{\psi_\alpha \circ ((\Theta^{(\alpha)}, b^{(\alpha)}), \theta^{(\alpha)}, W^{(\alpha)})\}_{\alpha = i, f, g}} (\mathbb{R}^H \times \mathbb{R}^H)^m \xrightarrow{(\cdot, \cdot, (\Theta^{(y)}, b^{(y)})} (\mathbb{R}^H \times \mathbb{R}^H \times \mathbb{R}^H)^m$$

$$X_t, h_{t-1}, c_{t-1} \longmapsto c_t, h_t \longmapsto c_t, h_t, y_t \tag{38}$$

The recurrence relation is essentially this:

$$X(t), h(t-1), c(t-1) \longmapsto c(t), h(t), y(t) \qquad \forall t = 0, 1, \dots T-1 \tag{39}$$

This is the recurrence relation that changes with time t and in the language of `theano`, for `theano.scan` it is the argument value for argument `sequences`.

Notice how h, c change over time. These are the sequences we want to take in as input and output. $X(t)$ is the sequences we want to "iterate over." $X(t)$ doesn't get modified by our operations over time t (than what is given). $y(t)$ is an output we desire. So in the language of `theano`, for `theano.scan`, $X(t)$ goes to the argument value for argument `sequences`, as it's part

of the "list of Theano variables or dictionaries describing the sequences `scan` has to iterate over" and since $X = X(t)$ for time t, the "`taps`" is `[0]`. h, c, y is expected to be the return value of the Python function describing a single time step, and "the order of the outputs is the same as the order of `outputs_info`.

Look at the parameters:

$$\begin{aligned} &(\Theta^{(g)}, b^{(g)}), \theta^{(g)} \in (\mathrm{Mat}_{\mathbb{R}}(d, H) \times \mathbb{R}^H \times \mathrm{Mat}_{\mathbb{R}}(H, H) \\ &(\Theta^{(\alpha)}, b^{(\alpha)}), \theta^{(\alpha)}, W^{(\alpha)} \in (\mathrm{Mat}_{\mathbb{R}}(d, H) \times \mathbb{R}^H \times \mathrm{Mat}_{\mathbb{R}}(H, H) \times \mathrm{Mat}_{\mathbb{R}}(H, H) \\ &(\Theta^{(y)}, b^{(y)}) \in (\mathrm{Mat}_{\mathbb{R}}(H, K) \end{aligned} \tag{40}$$

These parameters are what you put into, in the language of `theano`, for the argument value of `non_sequences` of `theano.scan`.

8.1. How to choose the number of hidden layers and nodes in a neural net.

Part 4. Support Vector Machines (SVM)

The clearest and most mathematically rigorous (and satisfying) introductory exposition on support vector machines (SVM) comes out of a Bachelor's thesis from Nowak (2008) [9]. There is a lot of material that tries to talk about SVM, but the implementation either boils down to showing how to turn the crank on a black-box solution, or is too verbose without saying anything substantial. I'll include references and links of the material I looked at and didn't find as helpful as Nowak (2008) [9].

Lecture12 pdf slides for Ng's Machine Learning Intro. for coursera

Support Vector Machine (and Statistical Learning Theory) Tutorial by Jason Weston, NEC Labs America

Wikipedia page for Support Vector Machine

Support Vector Machines and Generalisation in HEP Not much real generalization going on here other than a recap of literally what's exactly in Shawe-Taylor and Cristianini (2000) [10].

`https://www.cs.cornell.edu/people/tj/publications/joachims_99a.pdf`

9. From linear classifier as a hyperplane, (big) margin, to linear support vector machine (SVM), and Lagrangian dual (i.e. conjugate variables, conjugate momenta)

Intuitively, we seek to find a boundary line that'll draw a line that separates the data points into distinct K (usually $K = 2$) classes to classify the data points. Then, this boundary line will help to predict what class a new data point would fall into, be classified to be. For a linear model, i.e. "linear discriminator", what we're trying to do is

find

$$\theta \in \mathbb{R}^d \backslash \{0\},\ b \in \mathbb{R}$$

s.t.

$$y^{(i)}(\langle \theta, x^{(i)} \rangle + b) - 1 \geq 0 \qquad \forall\, i = 1, \ldots, m \tag{41}$$

where $\|\theta\|$ is minimal. It is minimal because, since the distance between 2 hyperplanes,

$$\langle \theta, x \rangle - b = \pm 1 \qquad \text{(defining equations for hyperplanes)}$$

is

$$\frac{2}{\|\theta\|} \qquad \text{(distance between 2 hyperplanes)}$$

Thus, we want the "margins", that distance between hyperplanes separating the input data points, to be as big as possible, and so we want $\|\theta\|$ small.

Consider this cost functional, called "Lagrangian", that we want to minimize:

$$\mathcal{L}((\theta, b), \lambda) = \frac{1}{2}\|\theta\|^2 - \sum_{j=1}^{m} \lambda_i y^{(i)}(\langle \theta, x^{(i)} \rangle - b - 1) = \frac{1}{2}\|\theta\|^2 - \sum_{j=1}^{m} \lambda_i y^{(i)}(\langle \theta, x^{(i)} \rangle - b) + \sum_{i=1}^{m} \lambda_i \tag{42}$$

Note that

$$f_0((\theta, b)) := \frac{1}{2}\|\theta\|^2 (\text{objective function (slightly modified)}) \tag{43}$$

is the objective function, what we want to minimize.

The KKT condition tells us that (θ, b) makes $\mathcal{L}$ a minimum for a certain λ:

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial \theta_j} &= 0 = \theta_j - \sum_{i=1}^{m} \lambda_i y^{(i)} x_j^{(i)} \\ \frac{\partial \mathcal{L}}{\partial b} &= 0 = -\sum_{i=1}^{m} \lambda_i y^{(i)} \end{aligned} \tag{44}$$

Note that this step in taking the partial derivatives of $\mathcal{L}$ in Eq. 44 is analogous to the construction/computation of dual "conjugate" variables, conjugate momentum, in physics.

Notice then that

$$\begin{aligned} &\frac{1}{2}\|\theta\|^2 = \frac{1}{2}\sum_{i,j=1}^{m} \lambda_i \lambda_j y^{(i)} y^{(j)} \langle x^{(i)}, x^{(j)} \rangle \text{ and} \\ &\sum_{i=1}^{m} \lambda_i y^{(i)}(\langle \theta, x^{(i)} \rangle - b) = \sum_{i=1}^{m} \lambda_i y^{(i)}(\sum_{j=1}^{m} \lambda_j y^{(j)} \langle x^{(j)}, x^{(i)} \rangle) \end{aligned} \tag{45}$$

$$\implies \mathcal{L}((\theta, b), \lambda) = -\frac{1}{2}\sum_{i,j=1}^{m} \lambda_i \lambda_j y^{(i)} y^{(j)} \langle x^{(i)}, x^{(j)} \rangle + \sum_{i=1}^{m} \lambda_i \tag{46}$$

10. So-called "Kernel trick"; feature space is a Hilbert space

The so-called "feature space" F is a Hilbert space H, $\Phi : \mathbb{R}^d \to H$, equipped with inner product

$$\langle \Phi(x), \Phi(y) \rangle = K(x, y) \tag{47}$$

with $K : \mathbb{K}^d \times \mathbb{K}^d \to \mathbb{K}^K$ being called the kernel function. Recall that the feature space F had been introduced to represent the process of preprocessing input data X. For example, given a single input data example, $X = (X_1, \ldots, X_d) \in \mathbb{R}^d$, maybe we'd want to consider polynomial features, linear combinations of various orders of monomials $X_i X_j$ or $X_i^2 X_j$, and so on. Then Φ represents the map from X to all these features.

The essense of the kernel trick is this: the explicit form of Φ need not be known, nor even the space H. Only the kernal function K form needs to be guessed at.

And so even if we now have to modify our Eq. 42 to account for this preprocessing map Φ, applied first to our training data $x^{(i)} \equiv X^{(i)}$ (Novak's notation vs. Andrew Ng's notation), we essentially still have the same form, formally.

Keep in mind the whole point of this nonlinear preprocessing map Φ - we want to keep the linear discrimination procedure with the weight, or parameter θ, and intercept b, being this linear model on the feature space (Hilbert space) F. We're linear in F. But we're nonlinear in the input data $X = \{X^{(1)}, \ldots X^{(m)}\}$.

So,

$$\begin{aligned} &\mathcal{L}((\theta, b), \lambda) = \frac{1}{2}\|\theta\|^2 - \sum_{j=1}^{m} \lambda_i y^{(i)}(\langle \theta, \Phi(x^{(i)}) \rangle - b - 1) = \frac{1}{2}\|\theta\|^2 - \sum_{j=1}^{m} \lambda_i y^{(i)}(\langle \theta, x^{(i)} \rangle - b) + \sum_{i=1}^{m} \lambda_i \text{ and so} \\ &\frac{\partial \mathcal{L}}{\partial \theta_j} = 0 = \theta_j - \sum_{i=1}^{m} \lambda_i y^{(i)} \Phi(x)_j^{(i)} \\ &\implies \mathcal{L}((\theta, b), \lambda) = -\frac{1}{2}\sum_{i,j=1}^{m} \lambda_i \lambda_j y^{(i)} y^{(j)} \langle \Phi(x^{(i)}), \Phi(x^{(j)}) \rangle + \sum_{i=1}^{m} \lambda_i \end{aligned} \tag{48}$$

10.1. **Dealing with Errors, (non-negative) slack variables, dealing with not-necessarily perfectly separable data.** First, loosen the strict constraint $y^{(i)}(\langle\theta, x^{(i)}\rangle - b) \geq 1$ by introducing *non-negative* slack variables ξ_i, $i = 1 \dots m$,

$$y^{(i)}(\langle\theta, x^{(i)}\rangle - b) \geq 1 - \xi_i, \qquad \forall\, i = 1, 2, \dots m \tag{49}$$

Simply add ξ to the objective function to implement penalty (for "too much slack"):

$$f_0(\theta, b, \xi) = \frac{1}{2}\|\theta\|^2 + C\sum_{i=1}^{m}\xi_i \tag{50}$$

So then the total Lagrangian becomes

$$\mathcal{L}(\theta, b, \xi, \lambda, \mu) = \frac{1}{2}\|\theta\|^2 + C\sum_{i=1}^{m}\xi_i - \sum_{i=1}^{m}\lambda_i(y^{(i)}(\langle\theta, x^{(i)}\rangle - b) - 1 + \xi_i) - \sum_{i=1}^{m}\mu_i\xi_i \tag{51}$$

where the constraint is turned into a Lagrange-multiplier type relation:

$$\xi_i \geq 0 \Longrightarrow \mu_i(\xi_i - 0) \qquad \forall\, i = 1, \dots m \tag{52}$$

$-\mu_i\xi_i$ is indeed a valid cost (penalty) functional (if $\xi_i < 0$, $-\mu_i\xi_i > 0$, and there's more penalty as ξ_i gets more negative. Note that I understood this cost or penalty accounting, given an *inequality constraint*, from reading notes from here, .

11. Dual Formulation

$$\begin{aligned} \text{min.} \qquad & W(\lambda) = -\sum_{i=1}^{m}\lambda_i + \frac{1}{2}\sum_{i,j=1}^{m}\lambda_i\lambda_j y^{(i)}y^{(j)}K(x^{(i)}, x^{(j)}) \\ \text{s.t.} \quad & \sum_{i=1}^{m}\lambda_i y^{(i)} = 0 \\ & 0 \leq \lambda_i \leq C \end{aligned} \tag{53}$$

At this point, Eq. 53 is what I could consider the "theoretical gold" version. Further modification of this formulation are really to efficiently implement this on the computer (or microprocessor!). But the schemes should respect this "gold" version and compute what this is and say.

11.1. **Implementation.** Wotao Yin's notes had a terse, but to-the-point, survey/summary of optimization, in particular nonlinear optimization with inequality constraints, for his courses 273a and Math 164, Algorithms for constrained optimization. In both course notes, the material is "taken from the textbook Chong-Zak, 4th. Ed." So we'll refer to Chong and Zak (2013) [11].

From Ch. 22 "Algorithms for Constrained Optimization", 2nd. Ed., from pp. 439, Sec. 22.2 Projections, consider $\Omega \subset \mathbb{R}^d$,

$$\Omega = \{\mathbf{x} | l_i \leq x_i \leq u_i,\, i = 1 \dots d\}$$

Let $\Pi \equiv$ projection operator. Define the above case as such:

$$\forall\, \mathbf{x} \in \mathbb{R}^d,\, y := \Pi[x] \in \mathbb{R}^d$$

$$y_i \equiv \begin{cases} u_i & \text{if } x_i > u_i \\ x_i & \text{if } l_i \leq x_i \leq u_i \\ l_i & \text{if } x_i < l_i \end{cases}$$

11.1.1. *Projected Gradient descent.* .

Implement $\sum_{i=0}^{m}\lambda_i y^{(i)} = 0$, consider the orthogonal projector matrix (operator)

$$\mathbf{P} := \mathbf{1}_{\mathbb{R}^d} - A^T(AA^T)^{-1}A \tag{54}$$

If $m = 1$, then

$$\text{Proj}_\Omega(\mathbf{y}) = \mathbf{y} - \frac{\mathbf{a}_1^T\mathbf{y} - b}{\|\mathbf{a}_1\|^2}\mathbf{a}_1$$

If $m > 1$, then

$$\text{Proj}_\Omega(\mathbf{y}) = (1_{\mathbb{R}^d} - A^T(AA^T)^{-1}A)\mathbf{y} + A^T(AA^T)^{-1}\mathbf{b}$$

For the linear (but it's an equality) constraint

$$\sum_{i=1}^{m}\lambda_i y^{(i)} = 0$$

so

$$\mathbf{P}_{\sum_{i=1}^{m}\lambda_i y^{(i)}=0}(\mathbf{y}) = \left(\mathbf{y} - \frac{\sum_{i=1}^{m} y^{(i)}(\mathbf{y})_i}{\sum_{i=1}^{m}(y^{(i)})^2}(y^{(i)})\mathbf{e}_i\right) \tag{55}$$

Narasimhan's Optimization Tutorial 3, Projected Gradient Descent, Duality had some concrete pseudocode for the projected gradient descent [12].

In summary,

we seek to minimize

$$W(\lambda) = -\sum_{i=1}^{m}\lambda_i + \frac{1}{2}\sum_{i,j=1}^{m}\lambda_i\lambda_j y^{(i)}y^{(j)}K(X^{(i)}, X^{(j)}) \qquad \forall\, i = 1, 2, \dots m \tag{56}$$

by iterating $t = 0, 1, \dots,$ as such:

$$\begin{aligned} \lambda_i'(t+1) &:= \lambda_i(t) - \alpha \text{grad} W(\lambda) \\ \lambda_i''(t+1) &:= \mathbf{P}_{\sum_{i=1}^{m}\lambda_i y^{(i)}=0}(\lambda_i'(t+1)) \\ \lambda_i(t+1) &:= \Pi_{0\leq\lambda_i\leq C}(\lambda_i''(t+1)) \end{aligned}$$

where

$$\mathbf{P}_{\sum_{i=1}^{m}\lambda_i y^{(i)}=0}(\lambda_i'(t+1)) = \lambda_i'(t+1) - \frac{\sum_{i=1}^{m} y^{(i)}\lambda_i'(t+1)}{\sum_{i=1}^{m}(y^{(i)})^2}y^{(i)}$$

$$\Pi_{0\leq\lambda_i\leq C}(\lambda_i''(t+1)) = \begin{cases} C & \text{if } \lambda_i''(t+1) > C \\ \lambda_i''(t+1) & \text{if } 0 \leq \lambda_i''(t+1) \leq C \\ 0 & \text{if } \lambda_i'(t+1) < 0 \end{cases} \tag{57}$$

11.1.2. *Computing b, the intercept, with a good algebra tip: multiply both sides by the denominator.* Bishop (2007) [13], on pp. 330 of Ch. 7, Sparse Kernel Machines, gave a very good (it resolved possible numerical instabilities) prescription on how to compute the intercept b, given λ, which would then give us the function that can make predictions $\widehat{y}$ on input data example $X^{(i)} \in X$. It's worth expounding upon here.

For any support vector (Bishop called it a support vector; what I think it's equivalent to is that we've trained on our training set $(X, y)^{\text{train}}$, and this is 1 of the training examples) $X^{(i)}$, $i = 1 \dots m$,

$$y^{(i)}f(X^{(i)}) = 1 \tag{58}$$

. Then using

$$
\begin{aligned}
f(x) &:= \sum_{i=1}^{m} y^{(i)} \lambda_i^* K(X^{(i)}, x) + b \\
\implies y^{(i)} &\left(\sum_{j=1}^{m} y^{(j)} \lambda_j^* K(X^{(j)}, X^{(i)}) + b \right) = 1
\end{aligned} \tag{59}
$$

Although we can solve this equation for b with algebra/arithmetic for our arbitrarily chosen support vector, it's numerically more stable to 1st. multiply through by $y^{(i)}$, using $(y^{(i)})^2 = 1$, and then averaging over all support vectors.

$$
\begin{aligned}
\sum_{j=1}^{m} y^{(j)} \lambda_j^* K(X^{(j)}, X^{(i)}) + b &= y^{(i)} \\
\implies b &= \frac{1}{m} \left(\sum_{i=1}^{m} y^{(i)} - \sum_{i,j=1}^{m} y^{(j)} \lambda_j^* K(X^{(j)}, X^{(i)}) \right)
\end{aligned} \tag{60}
$$

11.1.3. *Prediction (with SVM).*

$$
\begin{aligned}
\widehat{y}(X) &= \sum_{i=1}^{m} y^{(i)} \lambda_i^* K(X^{(i)}, X) + b^* \\
\widehat{y} &: \mathbb{R}^d \to \{0, 1, \ldots, K-1\}
\end{aligned} \tag{61}
$$

Clarke, Fokoue, and Zhang (2009) [14]

Part 5. **Notes**

Restricted Boltzmann machine - estimate a probability distribution
Recurrent neural network - creates an internal state of the network which allows it to exhibit dynamic temporal behavior
How to choose the number of hidden layers and nodes in a feedforward neural network?

"In sum, for most problems, one could probably get decent performance (even without a second optimization step) by setting the hidden layer configuration using just two rules: (i) number of hidden layers equals one; and (ii) the number of neurons in that layer is the mean of the neurons in the input and output layers."
